

AI Usage Log

MoMo SMS Analytics

Members: Aristote Henry Ngabo, Precious Amarachi Azubuike, Griphen Mweene

Tool Used

Claude (Anthropic), accessed via the Claude web/chat interface, used as a design and coding assistant throughout the project. All AI-generated material was reviewed, tested, and in most cases modified or rebuilt by the team before being adopted into the final submission.

Policy Compliance Statement

AI assistance was used for drafting, scaffolding, and reviewing work, not as a substitute for the team's own decisions. Every architecture, schema, and design choice below was evaluated, tested, or corrected by the team; several were changed after the team identified gaps in the AI's first draft.

Usage Log

System Architecture (Week 1)

Date/Stage	What was asked	What AI provided	Team verification / modification
Initial design	Draft a high-level system architecture for the ETL pipeline	A diagram showing XML input → ETL → database → frontend	Team identified the diagram treated the XML file as a static batch input rather than a user upload, and requested a correction
Revision	Rebuild the architecture to show the user uploading a file via the frontend	Updated diagram routing the upload through the frontend and API layer	Team redrew the corrected version independently in Eraser.io, expanding the database into real sub-tables and the frontend into named feature modules not originally suggested by AI
Enterprise layers	Add config, auth, logging, and testing as cross-cutting concerns	A diagram with these as a separate row plus a deployment pipeline diagram	Reviewed for the assignment's "enterprise-level" requirement; kept as reference, not submitted as-is

Entity Relationship Diagram & Database Design (Week 2)

Date/Stage	What was asked	What AI provided	Team verification / modification
ERD design	Design an ERD from the Week 2 task brief (Transactions, Users, Categories, System_Logs, plus a resolved M:N)	A reference ERD with attributes, PK/FK, cardinality, and a junction table	Used as a reference; the team's actual database_setup.sql schema (constraints, indexes, seed data) was independently authored by the team
Design rationale	Draft a 200-300 word justification for the schema decisions	A draft justification paragraph	Reviewed and included after team agreement with the reasoning
Data dictionary	Build a data dictionary from the team's own database_setup.sql	Tables listing every column, type, constraint, and description	Cross-checked against the team's actual SQL file for accuracy
Query demonstration	Show sample queries and constraint behavior	Ran the team's SQL against a test database to verify it worked as written	Team independently re-ran and screenshotted the same queries in VS Code's Database Client on their own machine; those real screenshots replaced the AI's placeholder output in the final document

Project Organization

Stage	What was asked	What AI provided	Team verification / modification
README	Draft a README describing the console/project	Draft README content	Reviewed by the team before committing to the repository

Summary

AI assistance was concentrated in early drafting: diagrams, documentation structure, and boilerplate scaffolding. The team's own contributions include the final database schema and seed data, all real query verification and screenshots, the redrawn architecture diagrams, sprint planning decisions, and every judgment call on what AI output to accept, reject, or rebuild.
